 SCIZER

# Scientific Solution for Size Reduction

## What is SCIZER treatment?

The Scizer is a non-invasive body contouring procedure. It helps to eliminate stubborn fat deposits around your waist without surgery. This is possible using MFU technology (Macro Focused Ultrasound).

Scizer treatment melts and destroys fat cells below the skin in the subcutaneous layer. As the fat cell count in these localised fat deposits is reduced, your body's contours are visibly improved.

## CLINICAL CASES

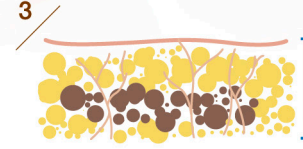

## Treatment Principles

1  
Even with a busy lifestyle and regular exercise, stubborn fat cells just don't seem to go away.

2  
The theory behind the treatment is to target the stubborn fat cells that reside within the subcutaneous fat layer.

3  
The manipulation of the adipocytes reduces the fat cell count in the targeted region.

4  
The fat cells subside and naturally exit the body, reducing the localized fat deposits allowing you to feel brand new.

## FAQ

### What does the Scizer treatment feel like?

Sensations experienced by patients from different forms of MFU treatment tend to vary, however with the contact cooling technology of the Scizer any discomfort is substantially reduced due to the numbing effect the hand-piece provides on the treatment area.

### How long does the treatment take?

Treatments can take as little as 20 minutes. Treatment lengths may vary based on the treatment area and what is comfortable for the patient.

### Who is a suitable candidate for Scizer treatment?

The Scizer treatment is recommended for all candidates who have stubborn fat in their abdominal region and are looking for other methods of treatment other than undergoing surgery which requires anesthesia and incisions. As long as you have a fat layer of more than 1 inch or 2.5 cm, you are suitable to receive Scizer treatment. Implants and other medical conditions may be an issue. Your consultant will advise you at your assessment.

### Are there any side effects?

Scizer applies ultrasound energy 13mm under the surface of the skin, melting the fat deposits in the subcutaneous fat layer at heat levels of 65°C.

Temporary redness, mild bruising, minimal discomfort and swelling may occur. All of these symptoms are resolved within 1-2 days of receiving treatment.
